

Authorization of Cross-Device Integration

Introduction

Cyber security is a vastly growing concern in our digital modernizing world, and everyday results in more data breaches. The need for increased digital security and various methods of doing so is a highly needed research and developing industry. An article written by John Zorabedian of <u>Security Intelligence</u>, estimated that the average cost of a security breach resulted in a loss of \$4.24 million. Even just recently during the Tokyo Olympics that was a breach of ticket holder's information according to an article on <u>ComputerWeekly.com</u> by Aaron Tan. Our research will show of the effectiveness of using user interaction for verifying individual users for future security implications.

Objective

The objective of our research is to identify the capabilities and possible applications of using user's gestures and interactions with their mobile device as a viable security measure.

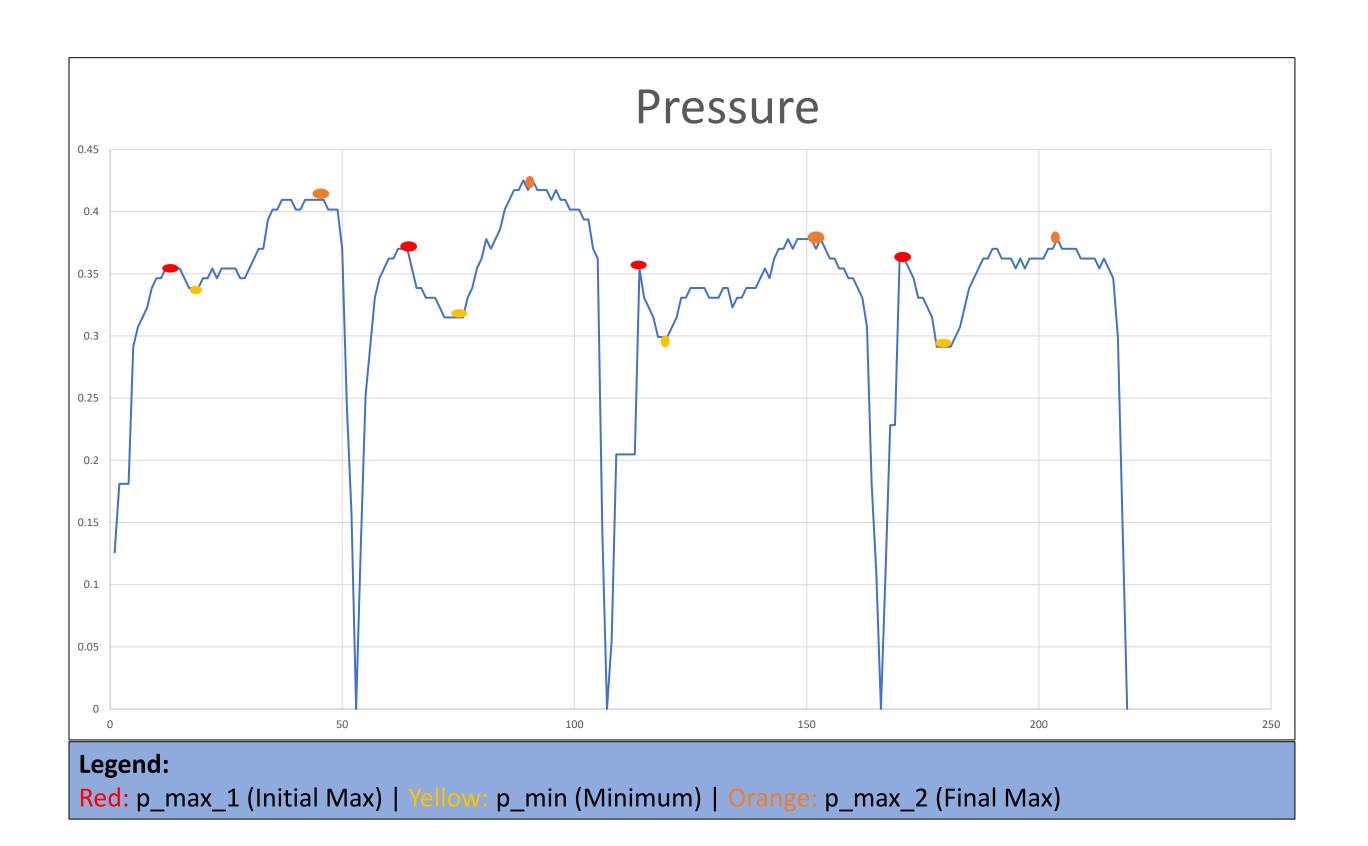

Materials/Methods

For the development of this application, our primary work was completed using Android Studios for our Integrated Development Environment (IDE), Java as our programming language, Weka (Machine Learning Software), and our Google Pixel phone.

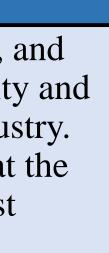

Our process was broken down into developing the code to collect, organize, and export the users' gestures using the Android Studio, and Google Pixel phone to run the program on for testing.

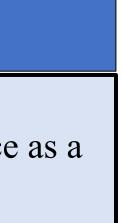

From there we began breaking down the data to find patterns among its sets, these became known as p_max_1, p_min, p_max_2, and std_dev. These data points looked to find the initial max, minimum, ending max, and finding the standard deviation of the entire gesture. These points then became what we use In our testing sets and how we identify users.

Finally, was gathering and storing this data and using Weka to verify success rates for comparisons of the data at identifying their users. This is done all through the software to save as time for trial-and-error testing, by doing thousands of comparisons and locating patterns between them.

Conclusion

The ability to use user gesture interaction has great potential for future implications of security measures. Including since our research didn't further into varying the coordinates of such user gestures. Working with the user not only just swiping the phone, but also with drawing other shapes on the screen will only increase the level of variations that can occur. More possibilities will lead to greater security of the user's data, which is the ultimate goal in this project's potential.

- Initial tests were to verify the effectiveness of using a user's *pressure*, touch size, and duration time of their gestures. These features proved to be very effective resulting in our training and testing sets being 100% accurate in depicting the correct users. However, we saw that in our cross-validation results only being 75% effectively; predicted 3 out of 4 users correctly.

- Next, we analyzed the usefulness of the coordinates and velocities collected for location and speed at which the users swiped their phones (initial hypothesis proved these features alone would prove not as effective giving users told to swipe in same location and only vertically). This data, surprisingly, found to be 100% accurate in training and testing data sets. Leading to be 94.7% accurate in

- Lastly, we come to see how all 5 features, broken into a total of 25 categories, are at verifying individuals. *Training, testing, and percentage split (80/20) tests* showed to be 100% accurate, and cross-validation came to 96.875% after 95 *folds of the program.* This without a doubt showed to be the best way at
